WildFly is a powerful, modular, & lightweight application server that helps you build amazing applications.

POWERFUL

Configuration in WildFly is centralized, simple and user-focused. The configuration file is organized by subsystems that you can easily comprehend and no internal server wiring is exposed. All management capabilities are exposed in a unified manner across many forms of access. These include a CLI, a web based administration console, a native Java API, an HTTP/JSON based REST API, and a JMX gateway. These options allow for custom automation using the tools and languages that best fit your needs.

MODULAR

WildFly does classloading right. It uses JBoss Modules to provide true application isolation, hiding server implementation classes from the application and only linking with JARs your application needs. Visibility rules have sensible defaults, yet can be customized. The dependency resolution algorithm means that classloading performance is not affected by the number of versions of libraries you have installed.

LIGHTWEIGHT

WildFly takes an aggressive approach to memory management. The base runtime services were developed to minimize heap allocation by using common cached indexed metadata over duplicate full parses, which reduces heap and object churn. The administration console is 100% stateless and purely client driven. It starts instantly and requires zero memory on the server. These optimizations combined enable WildFly to run with stock JVM settings and also on small devices while leaving more headroom for application data and supports higher scalability.

Welcome to the WildFly Documentation. The documentation for WildFly is split into two categories:

Administrator Guides for those wanting to understand how to install and configure the server

Developer Guides for those wanting to understand how to develop applications for the server

There is also the WildFly Model Reference that provides information about all subsystem configuration options generated directly from the management model.

Administrator Guides

The Getting Started Guide shows you how to install and start the server, how to configure logging, how to deploy an application, how to deploy a datasource, and how to get started using the command line interface and web management interface

The Admin Guide provides detailed information on using the CLI and Web Management interface, how to use the domain configuration, and shows you how to configure key subsystems

The High Availability Guide shows you how to create a cluster, how configure the web container and EJB container for clustering, and shows you how to configure load balancing and failover

Developer Guides

The Getting Started Developing Applications Guide shows you how to build Java EE applications and deploy them to WildFly. The guide starts by showing you the simplest helloworld application using just Servlet and CDI, and then adds in JSF, persistence and transactions, EJB, Bean Validation, RESTful web services and more. Finally, you'll get the opportunity to create your own skeleton project. Each tutorial is accompanied by a quickstart, which contains the source code, deployment descriptors and a Maven based build.

The Developer Guide (in progress) takes you through every deployment descriptor and every annotation offered by WildFly.

The JavaEE Tutorial (in progress) builds on what you learnt in the Getting Started Developing Applications Guide, and shows you how to build a complex application using Java EE and portable extensions.

The Extending WildFly guide walks you through creating a new WildFly subsystem extension, in order to add more functionality to WildFly, and shows how to test it before plugging it into WildFly.

The WildFly Testsuite guide walks you trough testing WildFly

Security Guide

The WildFly Elytron Security guide walks you trough new security layer of of WildFly

Client Guide

The WildFly Client Configuration guide walks you trough new wildfly client and how to use it.

Quickstarts

WildFly comes with a number of quickstarts, examples which introduce to a particular technology or feature of the application server. The Contributing a Quickstart section of the documentation details the available quickstarts

Welcome to the WildFly Documentation. The documentation for WildFly is split into two categories:

Administrator Guides for those wanting to understand how to install and configure the server

Developer Guides for those wanting to understand how to develop applications for the server

There is also the WildFly Model Reference that provides information about all subsystem configuration options generated directly from the management model.

Administrator Guides

The Getting Started Guide shows you how to install and start the server, how to configure logging, how to deploy an application, how to deploy a datasource, and how to get started using the command line interface and web management interface

The Admin Guide provides detailed information on using the CLI and Web Management interface, how to use the domain configuration, and shows you how to configure key subsystems

The High Availability Guide shows you how to create a cluster, how configure the web container and EJB container for clustering, and shows you how to configure load balancing and failover

Developer Guides

The Getting Started Developing Applications Guide shows you how to build Java EE applications and deploy them to WildFly. The guide starts by showing you the simplest helloworld application using just Servlet and CDI, and then adds in JSF, persistence and transactions, EJB, Bean Validation, RESTful web services and more. Finally, you'll get the opportunity to create your own skeleton project. Each tutorial is accompanied by a quickstart, which contains the source code, deployment descriptors and a Maven based build.

The Developer Guide (in progress) takes you through every deployment descriptor and every annotation offered by WildFly.

The JavaEE Tutorial (in progress) builds on what you learnt in the Getting Started Developing Applications Guide, and shows you how to build a complex application using Java EE and portable extensions.

The Extending WildFly guide walks you through creating a new WildFly subsystem extension, in order to add more functionality to WildFly, and shows how to test it before plugging it into WildFly.

The WildFly Testsuite guide walks you trough testing WildFly

Security Guide

The WildFly Flytron Security guide walks you trough new security layer of of WildFly

Client Guide

The WildFly Client Configuration guide walks you trough new wildfly client and how to use it.

Quickstarts

WildFly comes with a number of quickstarts, examples which introduce to a particular technology or feature of the application server. The Contributing a Quickstart section of the documentation details the available quickstarts

FORUMS

POWERFUL

Configuration in WildFly is centralized, simple and user-focused. The configuration file is organized by subsystems that you can easily comprehend and no internal server wiring is exposed. All management capabilities are exposed in a unified manner across many forms of access. These include a CLI, a web based administration console, a native Java API, an HTTP/JSON based REST API, and a JMX gateway. These options allow for custom automation using the tools and languages that best fit your needs.

MODULAR

WildFly does classloading right. It uses JBoss Modules to provide true application isolation, hiding server implementation classes from the application and only linking with JARs your application needs. Visibility rules have sensible defaults, yet can be customized. The dependency resolution algorithm means that classloading performance is not affected by the number of versions of libraries you have installed.

LIGHTWEIGHT

WildFly takes an aggressive approach to memory management. The base runtime services were developed to minimize heap allocation by using common cached indexed metadata over duplicate full parses, which reduces heap and object churn. The administration console is 100% stateless and purely client driven. It starts instantly and requires zero memory on the server. These optimizations combined enable WildFly to run with stock JVM settings and also on small devices while leaving more headroom for application data and supports higher scalability.
